

Simulating capital return and income growth to explore their impact on wealth inequality

Goals

Argued by the economist Thomas Piketty in his book *Capital in the Twenty-first Century*, the growth of income from capital (i.e. investments, property, etc.)¹ has been outpacing economic growth, leading to increased inequality. This report gather, simulate, and analyse data to test the validity of Piketty's theory and to understand the causes and implications of increasing inequality.

Methodology

1000 individuals randomly assigned per-timestep income Return on capital growth factor Gini coefficient to measure inequality Also measure economic mobility because "some degree of inequality might be acceptable if economic mobility were high" Incorporate exchange model to allow for certain level of uncertainty (The extension for tick 1)

1. Choose a return on capital smaller than the economic growth and see how the inequality changes overtime
2. Choose a return on capital higher than the economic growth and see how the inequality changes over time

Result

Conclusion

¹In this study we simplify the situation by assuming capital to be the current wealth
